CSE 252A Computer Vision I Fall 2018 - Assignment 3

Instructor: David Kriegman

Assignment Published On: Wednesday, November 7, 2018

Due On: Tuesday, November 20, 2018 11:59 pm

Instructions

- Review the academic integrity and collaboration policies on the course website.
- This assignment must be completed individually.
- This assignment contains theoretical and programming exercises. If you plan to submit hand written answers for theoretical exercises, please be sure your writing is readable and merge those in order with the final pdf you create out of this notebook. You could fill the answers within the notebook iteself by creating a markdown cell. Please do not mention your explanatory answers in code comments.
- Programming aspects of this assignment must be completed using Python in this notebook.
- If you want to modify the skeleton code, you can do so. This has been provided just to provide you with a framework for the solution.
- You may use python packages for basic linear algebra (you can use numpy or scipy for basic operations), but you may not use packages that directly solve the problem.
- If you are unsure about using a specific package or function, then ask the instructor and teaching assistants for clarification.
- You must submit this notebook exported as a pdf. You must also submit this notebook as .ipynb file.
- You must submit both files (.pdf and .ipynb) on Gradescope. You must mark each problem on Gradescope in the pdf.
- **Late policy** - 10% per day late penalty after due date up to 3 days.

Problem 1: Epipolar Geometry [3 pts]

Consider two cameras whose image planes are the z=1 plane, and whose focal points are at (-20, 0, 0) and (20, 0, 0). We''ll call a point in the first camera (x, y), and a point in the second camera (u, v). Points in each camera are relative to the camera center. So, for example if $(x, y) = (0, 0)$, this is really the point (-20, 0, 1) in world coordinates, while if $(u, v) = (0, 0)$ this is the point (20, 0, 1).

Fig1.png

a) Suppose the points $(x, y) = (12, 12)$ is matched to the point $(u, v) = (1, 12)$. What is the 3D location of this point?

b) Consider points that lie on the line $x + z = 0$, $y = 0$. Use the same stereo set up as before. Write an analytic expression giving the disparity of a point on this line after it projects onto the two images, as a function of its position in the right image. So your expression should only involve the variables u and d (for disparity). Your expression only needs to be valid for points on the line that are in front of the cameras, i.e. with $z > 1$.

Problem 2: Epipolar Rectification [4 pts]

In stereo vision, image rectification is a common preprocessing step to simplify the problem of finding matching points between images. The goal is to warp image views such that the epipolar lines are horizontal scan lines of the input images. Suppose that we have captured two images I_A and I_B from identical calibrated cameras separated by a rigid transformation

$$_A^B\mathrm{T} = \begin{bmatrix} R & t \\ 0^T & 1 \end{bmatrix}$$

Without loss of generality assume that camera A's optical center is positioned at the origin and that its optical axis is in the direction of the z-axis.

From the lecture, a rectifying transform for each image should map the epipole to a point infinitely far away in the horizontal direction $H_A e_A = H_B e_B = [1, 0, 0]^T$. Consider the following special cases:

a) Pure horizontal translation $t = [t_x, 0, 0]^T$, R = I

b) Pure translation orthogonal to the optical axis $t = [t_x, t_y, 0]^T$, R = I

c) Pure translation along the optical axis $t = [0, 0, t_z]^T$, R = I

d) Pure rotation $t = [0, 0, 0]^T$, R is an arbitrary rotation matrix

For each of these cases, determine whether or not epipolar rectification is possible. Include the following information for each case

- The epipoles e_A and e_B
- The equation of the epipolar line l_B in I_B corresponding to the point $[x_A, y_A, 1]^T$ in I_A (if one exists)
- A plausible solution to the rectifying transforms H_A and H_B (if one exists) that attempts to minimize distortion (is as close as possible to a 2D rigid transformation). Note that the above 4 cases are special cases; a simple solution should become apparent by looking at the epipolar lines.

One or more of the above rigid transformations may be a degenerate case where rectification is not possible or epipolar geometry does not apply. If so, explain why.

Problem 3: Filtering [3 pts]

a) Consider smoothing an image with a 3x3 box filter and then computing the derivative in the x direction. What is a single convolution kernel that will implement this operation?

b) Give an example of a separable filter and compare the number of arithmetic operations it takes to convolve using that filter on an $n \times n$ image before and after separation.

Problem 4: Sparse Stereo Matching [22 pts]

In this problem we will play around with sparse stereo matching methods. You will work on two image pairs, a warrior figure and a figure from the Matrix movies. These files both contain two images, two camera matrices, and set sets of corresponding points (extracted by manually clicking the images). For illustration, I have run my code on a third image pair (dino1.png, dino2.png). This data is also provided for you to debug your code, but you should only report results on warrior and matrix. In other words, where I include one (or a pair) of images in the assignment below, you will provide the same thing but for BOTH matrix and warrior. Note that the matrix image pair is harder, in the sense that the matching algorithms we are implementing will not work quite as well. You should expect good results, however, on warrior.

Corner Detection [5 pts]

The first thing we need to do is to build a corner detector. This should be done according to http://cseweb.ucsd.edu/classes/fa18/cse252A-a/lec11.pdf (http://cseweb.ucsd.edu/classes/fa18/cse252A-a/lec11.pdf). You should fill in the function `corner_detect` below, and take as input `corner_detect(image, nCorners, smoothSTD, windowSize)` where smoothSTD is the standard deviation of the smoothing kernel and windowSize is the window size for corner detector and non maximum suppression. In the lecture the corner detector was implemented using a hard threshold. Do not do that but instead return the nCorners strongest corners after non-maximum suppression. This way you can control exactly how many corners are returned. Run your code on all four images (with nCorners = 20) and show outputs as in Figure 2. You may find scipy.ndimage.filters.gaussian_filter easy to use for smoothing. In this problem, try different parameters and then comment on results.

1. windowSize = 3, 5, 9, 17
2. smoothSTD = 0.5, 1, 2, 4

Conclusion

For the same window size, while increasing the smoothSTD, it will help increase the corner detection's accuracy. Because the highr smoothSTD is, the stronger ability the Gaussian filter gain to remove the noise. Thus, it will be more likely to find the appropriate corners.

For the same smoothSTD, if the window size is too small, some of detected corners are overlapped which are not appropriate. Thus, by increasing the window size, the corners are more likly to be separate distribution.

NCC (Normalized Cross-Correlation) Matching [2 pts]

Write a function ncc *that implements the NCC matching algorithm for two input windows. NCC =* $\sum_{i,j}\tilde{W_1} (i,j)\cdot \tilde{W2} (i,j) where \tilde{W} = \frac{W - \overline{W}}{\sqrt{\sum_{k,l}(W(k,l) - \overline{W})^2}} is a mean-shifted and normalized version of the window and \overline{W}$ is the mean pixel value in the window W.

```python
def ncc_match(img1, img2, c1, c2, R):
    """Compute NCC given two windows.

    Args:
        img1: Image 1.
        img2: Image 2.
        c1: Center (in image coordinate) of the window in image 1.
        c2: Center (in image coordinate) of the window in image 2.
        R: R is the radius of the patch, 2 * R + 1 is the window size

    Returns:
        NCC matching score for two input windows.

    """
    x_1 = c1[0]
    y_1 = c1[1]
    x_2 = c2[0]
    y_2 = c2[1]
    W_1 = img1[y_1-R:y_1+R+1,x_1-R:x_1+R+1]
    W_2 = img2[y_2-R:y_2+R+1,x_2-R:x_2+R+1]
    if (W_1.shape[0] == W_2.shape[0]) and (W_1.shape[1] == W_2.shape[1]):
    #print(W_1.shape)
    #print(W_2.shape)
        W1_mean = np.mean(W_1)
        W2_mean = np.mean(W_2)
        w1_zeros = np.zeros((W_1.shape[0],W_1.shape[1]))
        w2_zeros = np.zeros((W_2.shape[0],W_2.shape[1]))
        for i in range(W_1.shape[0]):
            for j in range (W_1.shape[1]):
                w1_zeros[i,j] = (W_1[i,j] - W1_mean)**2
        w1_den = np.sqrt(np.sum(w1_zeros))
        for i in range(W_2.shape[0]):

0.6258689611426174
```

Naive Matching [4 pts]

Equipped with the corner detector and the NCC matching function, we are ready to start finding correspondances. One naive strategy is to try and find the best match between the two sets of corner points. Write a script that does this, namely, for each corner in image1, find the best match from the detected corners in image2 (or, if the NCC match score is too low, then return no match for that point). You will have to figure out a good threshold (NCCth) value by experimentation. Write a function naiveCorrespondanceMatching.m and call it as below. Examine your results for 10, 20, and 30 detected corners in each image. Choose a number of detected corners to the maximize the number of correct matching pairs. naive_matching will call your NCC mathching code.

Dino match

```python
def naive_matching(img1, img2, corners1, corners2, R, NCCth):
    """Compute NCC given two windows.

    Args:
        img1: Image 1.
        img2: Image 2.
        corners1: Corners in image 1 (nx2)
        corners2: Corners in image 2 (nx2)
        R: NCC matching radius
        NCCth: NCC matching score threshold

    Returns:
        NCC matching result a list of tuple (c1, c2),
        c1 is the 1x2 corner location in image 1,
        c2 is the 1x2 corner location in image 2.

    """

    """
    Your code here:
    """
    matching = []
    NCC = np.zeros((corners1.shape[0], corners2.shape[0]))
    for i in range(corners1.shape[0]):
        for j in range(corners2.shape[0]):
            NCC[i,j] = ncc_match(img1, img2, corners1[i], corners2[j], R)
            if NCC[i,j] > NCCth:
                matching.append((corners1[i], corners2[j]))

    return matching
```

```

Epipolar Geometry [4 pts]

Using the fundamental_matrix function, and the corresponding points provided in cor1.npy and cor2.npy, calculate the fundamental matrix.

Using this fundamental matrix, plot the epipolar lines in both image pairs across all images. For this part you may want to complete the function plot_epipolar_lines. Shown your result for matrix and warrior as the figure below.

Dino Epipolar

Dino Epipolar

Also, write the script to calculate the epipoles for a given Fundamental matrix and corner point correspondences in the two images.

```

Image Rectification [3 pts]

An interesting case for epipolar geometry occurs when two images are parallel to each other. In this case, there is no rotation component involved between the two images and the essential matrix is $E = [T_x]R = [T_x]$. Also if you observe the epipolar lines l and l' for parallel images, they are horizontal and consequently, the corresponding epipolar lines share the same vertical coordinate. Therefore the process of making images parallel becomes useful while discerning the relationships between corresponding points in images. Rectifying a pair of images can also be done for uncalibrated camera images (i.e. we do not require the camera matrix of intrinsic parameters). Using the fundamental matrix we can find the pair of epipolar lines l_i and l_i' for each of the correspondances. The intersection of these lines will give us the respective epipoles e and e'. Now to make the epipolar lines to be parallel we need to map the epipoles to infinity. Hence , we need to find a homography that maps the epipoles to infinity. The method to find the homography has been implemented for you. You can read more about the method used to estimate the homography in the paper "Theory and Practice of Projective Rectification" by Richard Hartley.

Image Rectification Setup

Using the compute_epipoles function from the previous part and the given compute_matching_homographies function, find the rectified images and plot the parallel epipolar lines using the plot_epipolar_lines function from above. You need to do this for both the matrix and the warrior images. A sample output will look as below:

sample rectification

In [383]:

```python
from numpy.linalg import inv
```

```

Matching Using epipolar geometry[4 pts]

We will now use the epipolar geometry constraint on the rectified images and updated corner points to build
a better matching algorithm. First, detect 10 corners in Image1. Then, for each corner, do a linesearch along
the corresponding parallel epipolar line in Image2. Evaluate the NCC score for each point along this line and
return the best match (or no match if all scores are below the NCCth). R is the radius (size) of the NCC patch
in the code below. You do not have to run this in both directions. Show your result as in the naive matching
part. Execute this for the warrior and matrix images.

In [587]:

```
def display_correspondence(img1, img2, matching):
    """Plot matching result on image pair given images and correspondences

    Args:
        img1: Image 1.
        img2: Image 2.
        corrs: Corner correspondence

    """
    show_matching_result(img1, img2, matching)
    """

    Your code here.
    You may refer to the show_matching_result function
    """

def correspondence_matching_epipole(img1, img2, corners1, F, R, NCCth):
    """Find corner correspondence along epipolar line.

    Args:
        img1: Image 1.
        img2: Image 2.
        corners1: Detected corners in image 1.
        F: Fundamental matrix calculated using given ground truth corner corresp
```

```python
        R: NCC matching window radius.
        NCCth: NCC matching threshold.

    Returns:
        Matching result to be used in display_correspondence function

    """
